Keywords: Connected and autonomous vehicles Shared autonomous vehicles Willingness to pay Ordered probit models

# ABSTRACT

Technological advances are bringing connected and autonomous vehicles (CAVs) to the ever-evolving transportation system. Anticipating public acceptance and adoption of these technologies is important. A recent internet-based survey polled 347 Austinites to understand their opinions on smart-car technologies and strategies. Results indicate that respondents perceive fewer crashes to be the primary benefit of autonomous vehicles (AVs), with equipment failure being their top concern. Their average willingness to pay (WTP) for adding full (Level 4) automation (\$7253) appears to be much higher than that for adding partial (Level 3) automation (\$3300) to their current vehicles.

Ordered probit and other model specifications estimate the impact of demographics, built-environment variables, and travel characteristics on Austinites' WTP for adding various automation technologies and connectivity to their current and coming vehicles. It also estimates adoption rates of shared autonomous vehicles (SAVs) under different pricing scenarios (\$1, \$2, and \$3 per mile), choice dependence on friends' and neighbors' adoption rates, and home-location decisions after AVs and SAVs become a common mode of transport. Higher-income, technology-savvy males, who live in urban areas, and those who have experienced more crashes have a greater interest in and higher WTP for the new technologies, with less dependence on others' adoption rates. Such behavioral models are useful to simulate long-term adoption of CAV technologies under different vehicle pricing and demographic scenarios. These results can be used to develop smarter transportation systems for more efficient and sustainable travel.

# 1. Introduction and motivation

Car travel is relatively unsafe, costly, and burdensome. Roughly 2.2 million Americans are injured in crashes each year, resulting in over 30,000 fatalities (NHTSA, 2014b). The economic cost of these crashes is roughly \$300 billion, which is approximately three times the U.S.'s annual congestion costs (Cambridge Systematics, 2011). Connected and autonomous vehicles (CAVs) provide a solution to the burden of car travel, and have the potential to reduce a high proportion of the 90% of crashes that result from driver error (NHTSA, 2008). CAVs represent the biggest technological advances in personal transport that the world has seen in over a century, with a promising future of safer and more convenient transportation.

CAVs are no longer a fantasy, and may soon become a daily mode of transport for hundreds of millions of people. Several mainstream companies, such as Google and Audi are developing and testing their own prototypes (Smiechowski, 2014). With rapid advances in vehicle automation and connectivity, the U.S. National Highway Traffic Safety Administration (NHTSA, 2013, 2014a) has recognized key policy needs for CAVs. California, Nevada, Florida, and Michigan have legislation to allow AV testing on public roads (Schoettle and Sivak, 2014a). Navigant Research (2014) estimated that 75% of all light-duty-vehicle sales around the globe (almost 100 million annually) will be autonomous-capable by 2035. In accordance with this timeline, Litman (2014) expects that AVs' beneficial impacts on safety and congestion are likely to appear between 2040 and the year 2060. If AVs prove to be very beneficial, Litman (2014) suggests that human driving may be restricted after the 2060.

Successful implementation of CAV technologies will require public acceptance and adoption over time, via CAV purchase, rental, and use (Heide and Henning, 2006). In the past three years, many researchers (Casley et al., 2013; Begg, 2014; Kyriakidis et al., 2014; Schoettle and Sivak, 2014a, 2014b; Underwood, 2014) and consulting firms (J.D. Power, 2012; KPMG, 2013; Vallet, 2013; Seapine Software, 2014; Continental, 2015) have conducted surveys and focus groups to understand the public perception about CAV's benefits and limitations. These studies provide descriptive statistics regarding public awareness, concerns, and expected benefits of smart-vehicle technologies, but they do not indicate how an individual's demographics (e.g., age, income, and education) and built-environment factors (e.g., employment density, population density, and area type) affect their opinions and willingness to pay (WTP) for such technologies.

This study designed and disseminated a survey for adult residents of Austin, Texas and received 358 completed responses. Those data facilitate a variety of perception and attitude analyses, using various econometric models. Response variables include respondents' WTP for Level 3 AVs,<sup>3</sup> Level 4 AVs, and CVs; adoption rates of shared AVs under different pricing scenarios; adoption timing of CAV technologies; and home location decisions after AVs become a common travel mode. Motivations for each behavioral model are provided below.

Estimating an individual's or household's WTP for Level 3 AVs, Level 4 AVs, and CVs is useful in identifying the demographic characteristics and land use settings of early, as well as late, adopters. Such information helps policymakers and planners predict near-term and long-term adoption of CAV technologies and devise policies to promote optimal adoption rates.

While AVs are set to emerge on the public market, they may quickly offer another mode of transportation: shared autonomous vehicles (SAVs). SAVs offer short-term, on-demand rentals with self-driving capabilities, like a driverless taxi (Kornhauser et al., 2013; Fagnant et al., 2015). SAVs may overcome the limitations of current carsharing programs, such as vehicle availability, because travelers will have the flexibility to call a distant SAV. Several studies (e.g., Burns et al., 2013; Fagnant and Kockelman, 2014) have shown how SAVs may reduce average trip costs by 30% to 85%, depending on the cost of automation and expected returns on the fleet operator's investment. Fagnant and Kockelman's (2015) agentbased simulation concluded that dynamic ridesharing (DRS) has the potential to further reduce total service times (wait times plus in-vehicle travel times) and travel costs for SAV users, even after incorporating extra passenger pick-ups, drop-offs, and non-direct routings. Chen et al. (2015) extended some of that work, and examined the performance (including profitability) of a fleet of shared electric AVs, across a 100-mile-diameter region. Pivoting off those simulations, this study explores the factors affecting SAV adoption rates under three pricing scenarios: \$1, \$2, and \$3 per occupied-mile traveled.

After AV adoption by neighbors and friends, individuals may gain confidence in such vehicles and/or sense social pressures, prompting them to purchase such technologies. Thus, this study estimates the adoption timing of AVs (e.g., will the respondent "never adopt" an AV, wait until 50% of his/her friends adopt an AV – or just 10% of his/her friends adopt one, or try to obtain an AV as soon as such vehicles are available on the market).

More efficient use of travel time (by allowing work or cell-phone conversations, for example) while riding in AVs may encourage individuals to shift their home locations to more remote locations, to enjoy lower land prices (and thereby bigger homes). Thus, AVs can exacerbate urban sprawl and increase a region's vehicle-miles traveled (VMT). However, a high density of low-cost SAVs in downtown areas may counteract such trends. Given the major land use shifts that could occur, this study also explores the factors associated with residential shifts, as motivated by AV and SAV access.

This work's behavioral model parameter estimates may vary in other spatial and temporal settings, as individuals are more aware of these technologies elsewhere and learn over time. However, these results are helpful to communities and nations in simulating long-term (e.g., years 2025 and 2040) adoption of CAV technologies, under different energy- and vehicle-pricing, demographic, and technology scenarios. For example, Bansal and Kockelman (2015) used such behavioral models in their simulation-based framework to forecast Americans' adoption rates of CAV technologies over 30 years. The following sections describe related studies, the survey's design, many summary statistics, choice model specifications, key findings, and study conclusions.

# 2. Literature review

This section summarizes the key findings of recent public opinion surveys about adoption of CAVs. Casley et al. (2013) conducted a survey of 467 respondents to understand their opinions about AVs. The results indicate that approximately 30% of respondents were willing to spend more than \$5000 to adopt full automation in their next vehicle purchase and

<sup>&</sup>lt;sup>3</sup> NHTSA (2013) defined five levels of automation: Levels 0, 1, 2, 3, and 4 imply no automation, function-specific automation, combined-function automation, limited self-driving automation, and full self-driving automation, respectively.

around the same proportion of respondents showed interest in adopting AV technology, four years after its introduction on the market. 82% of respondents reported safety as the most important factor affecting their adoption of AVs, 12% said leg-islation, and 6% said cost.

Begg (2014) conducted a survey of over 3500 British transport professionals to understand their expectations and issues related to the growth of driverless transportation in London. 88% of respondents expected Level 2 vehicles to be on the road in the U.K. by the year 2040; 67% and 30% believe the same for Level 3 and Level 4 vehicles, respectively. Furthermore, approximately 60% of respondents supported driverless trains in London, and the same proportion of respondents expected AVs to be safer than conventional vehicles.

Kyriakidis et al. (2014) conducted a survey of 5000 respondents across 109 countries by means of a crowd-sourcing internet survey. Results indicate that respondents with higher VMT and who use the automatic cruise control feature in their current vehicles are likely to pay more for fully-automated vehicles. Approximately 20% of respondents showed a WTP of more than \$7000 for Level 4 AVs, and approximately the same proportion of respondents did not want to pay more to add this technology to their vehicle. Most importantly, 69% of respondents expected that fully-automated vehicles are likely to gain 50% market share by the year 2050.

Schoettle and Sivak (2014a) surveyed 1533 respondents across the U.K., the U.S., and Australia to understand their perceptions about AVs. Results indicate that approximately two-thirds of respondents had previously heard about AVs. When respondents were asked about the potential benefits of Level 4 AVs, 72% expected fuel economy to increase, while 43% expected travel time savings to increase. Interestingly, 25% respondents were willing to spend at least \$2000 to add full self-driving automation in the US, while same proportion of respondents in the UK and Australia were willing to spend \$1710 and \$2350, respectively. However, 54.5% respondents is the U.S., 55.2% in the U.K., and 55.2% in Australia did not want to pay more to add these technologies. When asked about their activities (e.g., work, read, and talk with friends) while riding in Level 4 AVs, the highest proportion, 41%, of respondents said they would watch the road even though they would not be driving. Results of one-way analysis of variance indicated that females are more concerned about AV technologies than males.

Underwood (2014) conducted a survey of 217 experts. 80% of respondents had a master's degree, 40% were AV experts, and 33% were CV experts. According to these experts, legal liability is the most difficult barrier to fielding Level 5 AVs (full automation without a steering wheel), and consumer acceptance is the least. Approximately 72% of the experts suggested that AVs should be at least twice as safe as the conventional vehicles before they are authorized for public use. 55% of the experts indicated that Level 3 AVs are not practical because drivers could become complacent with automated operations and may not take required actions.

Carlnsurance.com's survey of 2000 respondents found that approximately 20% of respondents were interested in buying AVs (Vallet, 2013). Interestingly, when respondents were presented with an 80% discount on car insurance for AV owners, 34% and 56% of respondents indicated strong and moderate interest in buying AVs, respectively. When respondents were asked to choose the activities they would like to perform while riding in AVs, the highest share of respondents (26%) chose to talk with friends. Survey results also indicate that approximately 75% of respondents believed that they could drive more safely than AVs. Only 25% would allow their children to ride to school in AVs, unchaperoned. When asked who they would trust most to deliver the AV technology, the highest proportion (54%) of respondents said traditional automobile companies (e.g., Honda, Ford, and Toyota), instead of other companies (e.g., Google, Microsoft, Samsung, and Tesla). Seapine Software's (2014) survey of 2038 respondents reported that approximately 88% of respondents (84% of 18–34 year-olds and 93% of 65 year-olds), were concerned about riding in AVs. 79% of respondents were concerned about AV equipment failure, while 59% and 52% were concerned about liability issues and hacking of AVs information systems, respectively.

J.D. Power (2012) conducted a survey of 17,400 vehicle owners before and after revealing the market price of 23 CAV technologies. Prior to learning about the market price, 37% of respondents showed interest in purchasing the AV technology in their next vehicle purchase, but that number fell to 20% after learning that this technology's market price is \$3000. 18–37 year old male respondents living in urban areas showed the highest interest in purchasing AV technology.

A KPMG (2013) focus group study, using 32 participants, notes that respondents became more interested in AVs when they were provided incentives like a designated lane for AVs, and learned their commute time would be cut in half. In contrast to Schoettle and Sivak's (2014a) findings, the focus group's discussion and participants' ratings for AV technology suggests that females are more interested in these technologies than males. While focus group females emphasized the benefits of self-driving vehicles (e.g., mobility for physically challenged travelers), males were more concerned about being forced to follow speed limits. Interestingly, the oldest participants (60+ year-old) and the youngest (21–34 year-olds) expressed the highest WTP in order to obtain self-driving technologies. Continental (2015) surveyed 1800 and 2300 respondents in Germany and the United States, respectively. Approximately 60% of respondents expected to use AVs in stressful driving situations, 50% believed that AVs can prevent accidents, and roughly the same number indicated they would likely engage in other activities while riding in AVs.

Recently, Schoettle and Sivak (2014b) surveyed 1596 respondents across the U.K, the U.S., and Australia to understand their perceptions about CVs. Surprisingly, only 25% of respondents had heard about CVs. When asked about the expected benefits of CVs, the highest proportion, 85.9%, of respondents expected fewer accidents and the lowest proportion, 61.2%, expected less distraction for the driver. Approximately 84% of respondents rated safety as the most important benefit of CVs, 10% said mobility, and 6% said environmental benefits. Interestingly, 25% respondents were willing to spend at least \$500, \$455, and \$394 in the U.S., the U.K., and Australia, respectively, to add CV technologies. However, 45.5%, 44.8%, and 42.6% of respondents did not want to pay anything extra to add these technologies in the U.S., the U.K., and Australia, respectively.

As mentioned above, these past studies reveal important information about individual perceptions of CAV technologies, but none has explored various related aspects, such as adoption rates of SAVs under various pricing scenarios, home-location choices when SAVs and AVs become common modes of transport, and peer-pressure effects on the adoption time of AVs. Moreover, econometric analysis is missing in all of these studies, but is crucial for devising efficient policies to increase market penetration of emerging transportation technologies. This study explores statistical and practical significance of relationships between respondents' demographics and built-environmental attributes, and their WTP for CAVs, adoption rates of SAVs, residence-shift decisions, and adoption timing of AVs using univariate and bivariate ordered probit (OP) models. These behavioral models will be very useful in forecasting adoption of CAV technology and land use changes under different pricing scenarios.

#### 3. Survey design and data processing

The data were collected via a survey in Austin, Texas from October to December 2014 using "Qualtrics", a web-based survey tool. Exploring respondents' preferences for adoption of emerging vehicle and transport technologies, the survey asked 52 questions regarding respondents' perceptions of AV technology upsides and downsides, ridesharing, and carsharing. Respondents were also asked about their WTP for CAVs, adoption rates of SAVs in different pricing scenarios, future home-location decisions, adoption timing of AVs, current travel patterns, and demographics.

Austin neighborhood associations were first contacted via email and passed the survey requests to their respective residents. A total of 510 respondents initiated the survey; only 358 of them completed it. However, 11 of those were not Austinites and thus were excluded from the sample, resulting in a total sample of 347 adults (over 18 years of age). The sample over-represented women, middle-aged persons (25–44 year-old) and those with a bachelor's degree or higher.

Therefore, the survey sample proportion in each demographic class was scaled using the 2013 American Community Survey's Public Use Microdata Sample (PUMS, 2013) for the Austin. The population weights were calculated by dividing the sample into 72 categories based on gender, age, education, and household income (HHI). To understand the impact of built-environment factors (e.g., employment density, population density, and area type) on preferences, respondents' home addresses were geocoded<sup>4</sup> using Google Maps API and spatially joined with Austin's traffic analysis zones (TAZs) using open source Quantum GIS.

#### 4. Data set statistics

Table 1 summarizes the demographic, built-environment, zone-level,<sup>5</sup> and technology-related variables after correction for biased-sample's demographics. This study uses these variables as the predictors in many model specifications. Prior to using these predictors, each respondent's record was population-weighted to provide relatively unbiased model calibration.

# 4.1. Current technology awareness

To better understand the future adoption of smart transportation technologies and strategies, it is important to explore respondents' current awareness about them. Table 1 indicates that in general, Austinites are tech-savvy; 92% of the population-weighted sample carry or own a smartphone, 80% have heard of Google's self-driving car, and 60% consider anti-lock braking systems (ABS, required on all cars sold in the U.S. since September, 2011) to be a form of vehicle automation (which it is: Level 1 automation). Probably, due to popularity of carsharing (Car2Go and Zipcar) and ridesharing (UberX and Lyft) companies in Austin, 95% and 85% of respondents are familiar with both of them, respectively.

#### 4.2. Key response variables

Table 2 summarizes the key response variables estimated in this study. At a cost of more than \$5000, 24% and 57% of respondents were willing to add Level 3 and Level 4, respectively, to their next vehicle purchase. As expected, the average WTP (of the population-corrected sample) for Level 4 automation (\$7253) is much higher than that for Level 3 automation (\$3300). Apparently, AVs may not impact residential land-use patterns much, since 74% of respondents expect to stay at their current location even after AVs and SAVs become common modes of transport.<sup>6</sup> 30% showed interest in using AVs as soon as they are available for mass market sales in the U.S. Interestingly, approximately half of the respondents would prefer their fam-

<sup>&</sup>lt;sup>4</sup> For respondents, who did not provide their street address or recorded incorrect addresses, their internet protocol (IP) locations were used as the proxies for their home locations.

<sup>&</sup>lt;sup>5</sup> The TAZ-level variables were obtained by spatial mapping of respondents' home locations with a TAZ-level shape files, obtained from Austin's Capital Area Metropolitan Planning Organization.

<sup>&</sup>lt;sup>6</sup> Prior to asking a question about residence-shift decisions, respondents were informed that self-driving vehicles will make travel much easier for many people. By being able to sleep on the road, some travelers may decide to live farther from the city center, their workplaces, their children's schools, or other destinations (in order to access less expensive land for a larger home or parcel, for example). On the other hand, by living in more urban locations, one will be able to more quickly (and less expensively) access a shared fleet of self-driving vehicles (at a rate of say, \$1.50 per mile of travel), allowing them to let go of cars they presently own, and turn to other transport options.

P. Bansal et al./Transportation Research Part C 67 (2016) 1-14

#### Table 1

Population-weighted summary statistics of explanatory variables ( $N_{obs} = 347$ ).

Туре	Explanatory Variables	Description	Mean	SD	Min.	Max.

to use SAVs at least once a week. Only 26% of respondents rejected a proposal of adding connectivity<sup>8</sup> to their vehicles at a cost of less than \$100.

#### 4.3. Other opinions about AVs and CVs

Table 3 summarizes the individuals' perceptions about the benefits and concerns of CAVs. 19% of respondents were not at all interested in owning Level 4 AVs. Respondents indicated three main issues regarding AVs: 50% of respondents were concerned about equipment or system failure, while 48% and 38% were concerned about interactions with conventional vehicles and affordability, respectively. Only 7% of respondents were apprehensive about learning to use AVs. 31% of respondents believe that AVs cannot help with calming congestion, making this the "least likely" AV benefit (among plausible options tested). When asked about the other three benefits (fewer crashes, lower emission, and better fuel economy), respondents considered them almost equally likely, but a reduction in crashes received maximum (63%) support. 75% of respondents indicated wanting to talk or text with friends and look out of the window while riding in AVs – making these the two most appealing tasks for respondents while traveling in Level 4 AVs. More than 70% of respondents would like to ride in AVs on freeways, high-speed highways, and congested traffic, while only 46% would let the vehicles drive themselves on city streets. Surprisingly, only 47% of respondents have heard about CVs.<sup>9</sup> It is worth noting that only 4.3% of respondents are currently surfing the internet and 6.2% are emailing while driving (conventional vehicles), but 31.7% and 39% are interested in adding these technologies to their vehicles, respectively.

<sup>&</sup>lt;sup>8</sup> Before asking about WTP for CVs, respondents were advised that connectivity can be added to an existing vehicle, requiring one's smartphone plus extra equipment (a DSRC chip and inertial sensor) costing less than \$100.

<sup>&</sup>lt;sup>9</sup> Before asking questions about CVs in the survey, we provided very detailed information about them, like the following: Connectivity can be added to an existing vehicle that would require one's smartphone plus extra equipment (DSRC chip and inertial sensor) costing less than \$100.

Population-weighted results of opinion-based questions on carsharing and ridesharing.

Туре	Opinion-based questions	Yes	No	Skipped
A carsharing member because	Carsharing program member Program saves money Program saves time Environment friendly program Do not own a vehicle	14.8% 6.4% 6.2% 7.1% 1.8%	80% 8.4% 8.6% 7.7% 13%	5.2% 85.2% 85.2% 85.2% 85.2%

*Note:* Nobs = 347. In the survey, carsharing and ridesharing questions were dynamically designed with skip logic and conditional branching. For example, respondents who were not familiar with carsharing were not asked whether they are carsharing members or not. Such responses were considered in the "Skipped" category.

## 4.4. Carsharing and Ridesharing Opinions

Table 4 summarizes opinions regarding adoption of carsharing (Car2Go or Zipcar) and ridesharing (UberX or Lyft). 14.8% of respondents were a member of a carsharing program at the time of the survey (Fall 2014). Among these respondents, 42% chose such a program because they believe it saves time and money, and 48% because they believe it is environmentally friendly. Interestingly, only 12% of carsharing members (1.8% of all respondents) are part of the program because they do not own a vehicle. Most non-carsharing members either own a vehicle or rely on transit and walking. Only 20% of non-carsharing members did not choose such programs because they perceived carsharing to be costlier than the other modes, and 17.5% and 6.5% did not choose due to vehicles' unavailability near their homes, and the unreliability of vehicle availability at other places, respectively.

Almost 30% of respondents had used Uber or Lyft at least once as a passenger, and 50–60% of such users chose these services in order to save time or/and money (versus a bus or taxi, for example), to avoid driving after drinking alcohol, or to simply try them out. 50% of respondents were comfortable in sharing a ride with a stranger for short durations during the day or with a friend of one of their Facebook friends. Interestingly, 9.2% of respondents did not want to share a ride with their friends or family members.

#### 5. Model estimation

This study estimated adoption rates of SAVs under three pricing scenarios (\$1, \$2, and \$3 per mile), interest in having one's existing vehicle become a CV (for under \$100), adoption timing of AVs, and future home-location shifts (after AVs and SAVs become common modes of transport) using univariate OP specifications in Stata 12 software (Long and Freese, 2006). The univariate OP model specifications are presented here in the context of interest in adding connectivity. The main equation for this specification is as follows (Greene, 2012):

$$y_i^* = \beta' x_i + \varepsilon_i$$

(1)

where subscript 'i' denotes an individual observation,  $y_i^*$  represents the individual's latent inclination to add connectivity at a cost of less than \$100,  $x_i$  represents a vector of covariates for each individual,  $\beta'$  represents a vector of regression coefficient, which are to be estimated, and  $\varepsilon_i$  represents a random error term assumed to follow a standard normal distribution.

For this example, two thresholds ( $\mu_1$  through  $\mu_2$ ) were estimated to distinguish the three categories, where  $\mu_1$  represents the threshold between "not interested" and "neutral" and  $\mu_2$  – is the threshold between "neutral" and "interested in adding connectivity at a cost of less than \$100". Under this specification, the opinion probabilities are as follows:

Pr (not interested) =  $Pr(y_i^* \leq \mu_1)$ 

(2)

 $(\mathbf{3})$ 

(4)

 $Pr(neutral) = Pr(\mu_1 \leq y_i^* \leq \mu_2)$ 

$$Pr(\text{interested}) = \Pr(y_i^* \ge \mu_2)$$

The WTP for AVs (Level 3 and Level 4) had two related response variables and so were jointly estimated using seemingly unrelated specifications<sup>10</sup> of the bivariate OP model<sup>11</sup> (as described in Sajaia (2008)).

Initial model specifications included all Table 1's explanatory variables. The models were re-estimated using stepwise elimination by removing the covariate with the lowest statistical significance until all *p*-values were less than 0.32, which corresponds to a |Z-stat| of 1.0. Although most of the explanatory variables enjoy a *p*-value greater than .10 (|Z-stat| > 1.645), it was not used as a statistical significance threshold here, due to the slightly limited sample size (n = 347). If more sample observations were available (say n = 1000), statistical significance could have improved for many explanatory variables. Explanatory variables with *p*-value less than .01 (|Z-stat| > 2.58) are considered highly statistically significant predictors.

Practical significance is generally more meaningful than statistical significance. This study considers an explanatory variable practically significant if a one-standard-deviation increment in it leads to a significant shift in the response variable. In this paper, response variables are probabilities of ordered choice options, so an explanatory variable is considered to be practically significant if the predicted probabilities (i.e., the  $\Delta Pr_i$  shown in Tables 5–9) change by more than a factor of 1.3 or less than a factor of 0.7. In other words, there is at least 30% shift in the predicted probability (which could be from 0.50 to 0.67 or to 0.35). If the shift in the model-predicted probability exceeds 50% (i.e., the ratio of the two is more than 1.5 or less than 0.50), the explanatory variable is defined here as *highly* practically significant. McFadden's *R*-square<sup>12</sup> and adjusted *R*-square are also provided, to characterize all models' goodness of fit.

## 5.1. Willingness to pay for AVs

Table 5 summarizes the bivariate OP model estimates of WTP for adding Level 4 automation (of < \$2000, \$2000–5000, \$5000–10,000, or > \$10,000) and WTP for Level 3 automation (< \$2000, \$2000–5000, or > \$5000). Results indicate that male respondents with a greater number of children, living in higher-income neighborhoods, and who drive alone for social trips, ceteris paribus, are willing to pay more to add Level 3 and Level 4 automation to their next vehicle. In contrast, licensed drivers living in more job-dense neighborhoods, and who are familiar with carsharing and ridesharing companies are estimated to pay less to add Level 3 and Level 4 automation to their next vehicles, ceteris paribus.<sup>13</sup> Perhaps individuals who are familiar with carsharing and ridesharing would rather rely on low-cost SAVs instead of buying a new vehicle with added automation technology. Interestingly, individuals who travel more (exhibit higher annual VMT) and who live farther from their workplace exhibit higher WTP for adding Level 4 AVs, but lower WTP for Level 3 AVs. Perhaps the opposite signs, but practical significance of both attributes for the WTP of Level 3 and Level 4 AVs reflect the individuals' perception that they would be able to use their travel time (for work, sleep, or other meaningful activities) in a Level 4 AVs, but not in Level 3 AVs.

In addition, everything else is equal, older persons are predicted to have a significantly lower WTP for AVs (in a practically and statistically significant sense). Perhaps they are concerned about learning to use AVs and do not trust these technologies. Practically significant and positive associations between the number of crashes experienced by an individual and their WTP for AVs indicates that such persons may be anticipating the safety benefits of AVs.<sup>14</sup> Respondents who drive alone for work trips are estimated to have a (practically and statistically) significantly higher WTP for AVs, indicating the possibility of shifting commuters to SAV fleets in the future. A high correlation coefficient estimate across these two OP equations ( $\rho$  = +0.921) strongly supports the use of a seemingly unrelated bivariate OP specification here.

# 5.2. SAV adoption rates under different pricing scenarios

Table 6 shows the OP model estimates of SAVs' adoption rates (i.e., relying on it less than once a month, at least once a month, at least once a week, or entirely on SAV fleet) in three pricing scenarios (\$1 per mile [Model 1], \$2 per mile [Model 2], and \$3 per mile [Model 3]). Results indicate that full-time male workers living in urban areas, ceteris paribus, are likely to use SAVs more frequently, but consistent with the findings of the WTP for AVs' model, licensed drivers are estimated to use SAVs less frequently under all three pricing scenarios (everything else held constant). Perhaps many licensed drivers are concerned about losing the excitement of driving after AVs become a common mode of transport.<sup>15</sup> Or they may have a hard

<sup>&</sup>lt;sup>10</sup> In seemingly unrelated specifications, error terms are only correlated across choices of the individual, but are independent and homoscedastic across the individuals.

<sup>&</sup>lt;sup>11</sup> To estimate WTP for SAVs, complex trivariate OP model specifications could be used, but it would have only slightly improved statistical significance of predictors, without affecting the magnitude and sign of the coefficients much. Therefore, to control the complexity, three univariate OP models were estimated for each of the three cost scenarios (\$1, \$2, and \$3 per mile).

<sup>&</sup>lt;sup>12</sup> McFadden's *R*-square =  $1 - \frac{\log(L_{hall})}{\log(L_{hall})}$  and McFadden's adjusted *R*-square =  $1 - \frac{(\log(L_{hall})) - n}{\log(L_{hall})}$ , where *n* is the number of parameters in the fitted model, and  $L_{full}$  and  $L_{null}$  denote the likelihood values of the fitted model and only-intercept (with no explanatory variable) model, respectively.

<sup>&</sup>lt;sup>13</sup> This study's finding about the relationship between respondents' gender and WTP for AVs are aligned with that of J.D. Power's (2012) and Schoettle and Siyak's (2014a) study. Similarly, Kyriakidis et al. (2014) observed the positive correlation between income and WTP for AVs, which is quite intuitive.

<sup>&</sup>lt;sup>14</sup> As discussed earlier, the highest population-weighted proportion (63%) of respondents rated fewer crashes as a "very likely" benefit of AVs.

<sup>&</sup>lt;sup>15</sup> Litman (2014) anticipates that if AVs are successful, human driving could be restricted after 2060.

Willingness to pay for autonomous vehicles (bivariate ordered probit model results).

*Notes*:  $N_{obs}$  = 347. "Log (Annual VMT)" was used as an explanatory variable in the model, but corresponding  $\Delta Pr$ 's were calculated with respect to "Annual VMT". All Z-stats with |Z-stat| > 2.58 are in bold, and indicate highly statistically significant predictors. All  $\Delta Pr$ 's with  $|\Delta Pr_i| > 30\%$  are in bold, and indicate practically significant predictors.

time envisioning life without a privately held vehicle, and becoming largely reliant on SAVs. The practically significant positive associations of indicator variables (whether an individual has heard about Google's self-driving car and if an individual thinks that ABS is form of automation), in all three pricing-scenarios, suggests that tech-savvy individuals are more likely to be frequent SAV users. Similarly, those living in more densely populated neighborhoods expect higher SAV adoption rates (in all three models), perhaps due to less convenient parking facilities and lower vehicle ownership rates in these areas (Celsor and Millard-Ball, 2007).

A highly practically significant and positive relationship between the home-distance from one's workplace and SAV adoption rates in Models 1 and 2 suggests that these workers are more likely to use SAVs more often at current carsharing and ridesharing prices. Although this variable (respondents' distances from their workplace) does not appear in Model 3's final specification, another covariate, distance from downtown, may be capturing its effect.<sup>16</sup> The individuals living farther from downtown, all other attributes remaining constant, are expected to use SAVs less frequently at \$3 per mile. Consistent with findings of the WTP for AVs' model, older persons are predicted to use SAVs less frequently, but individuals who have experienced more crashes in the past, ceteris paribus, have a practically significant inclination to use SAVs more frequently, even at \$2 and \$3 per mile (more than what carsharing companies and UberX or Lyft currently charge). The practical significance and negative association of the familiarity-with-carsharing indicator with SAV adoption rates in Models 2 and 3 suggest that individuals who already know carsharing's current price may not be willing to pay more to use comparably convenient SAVs. A highly practically significant and negative relationship of an individual's annual VMT with SAV adoption rate (found only in Model 3) is as expected because SAVs at \$3 per mile may lead to a high annual travel cost for these individuals.

<sup>16</sup> The correlation coefficient of distance from work-place and distance from downtown is 0.53.

SAV adoption rates under different pricing scenarios (ordered probit model results).

*Notes:*  $N_{obs} = 347$ . All Z-stats with |Z-stat| > 2.58 are in bold, and indicate highly statistically significant predictors. All  $\Delta Pr's$  with  $|\Delta Pr_i| > 30\%$  are in bold, and indicate practically significant predictors.

#### 5.3. Willingness to pay for CVs

Table 7 summarizes the OP model estimates of the WTP for CVs (i.e., not interested, neutral, or interested in adding connectivity to current vehicle at a cost of less than \$100). These estimates indicate that respondents living farther from their workplace in higher household density urban neighborhoods, who carry a smart phone, and drive alone for work and social trips, ceteris paribus, are estimated to have greater interest in adding connectivity to their current vehicles. Perhaps the individuals who have higher annual VMT, have experienced more accidents, and have heard about Google's self-driving car, all other predictors remaining constant, are able to evaluate and appreciate the safety benefits of low-cost connectivity. Therefore, the corresponding predictors enjoy positive and practically significant relationships with WTP for CVs.

#### 5.4. Adoption timing of AVs

Table 8 summarizes the OP model estimates of the adoption timing of AVs (i.e., never adopt AVs, adopt AVs when 50% of friends adopt, when 10% of friends adopt, or as soon as available on the market). AV adoption by older licensed drivers living farther from their workplace in high basic employment density neighborhoods, ceteris paribus, is more likely to depend on their friends' adoption rates. However, males with higher HHI, living in urban neighborhoods, and who travel more, all other attributes remaining constant, are estimated to have a practically significant inclination to adopt AVs, with less dependence on their friends' adoption rates. The number of accidents experienced by the individual and the indicator variables, whether an individual has heard about Google's self-driving car and if an individual thinks that ABS is a form of automation, exhibit a positive and practically significant association with AV adoption timing. This relationship indicates that tech-savvy individuals, who perceive the safety benefits of AVs, are more likely to adopt them with less dependence on their friends' adoption rates.

#### 5.5. Home location shifts due to AVs and SAVs

Table 9 summarizes the OP model estimates of respondents' home-location-shift decisions (i.e., shift closer to central Austin, stay at the same location, or move farther from central Austin) after AVs and SAVs become common modes of transport. Results indicate that respondents with a greater number of children, living farther from their workplace in high employment density neighborhoods, and who drive alone for work trips, ceteris paribus, are predicted to shift farther from central Austin. Perhaps these individuals are excited about lower land prices in suburbs and are comfortable using their longer commute times to pursue other activities (e.g., working, talking with friends, and reading). People with Bachelor's degrees or higher, living in high household density neighborhoods, all other attributes remaining the same, also exhibit a practically significant inclination to shift farther from central Austin. Perhaps these individuals are a safter AVs and SAVs become common modes of transport. In contrast, full-time working males, with higher HHI and higher VMT, all other predictors remaining constant, are likely to shift closer to central Austin, perhaps to appreciate and adopt low-cost SAVs' higher level of service. As expected, tech-savvy respondents (i.e., who carry a smartphone and are familiar with carsharing options), living in urban neighborhoods, ceteris paribus, are estimated to have a practically significant propensity to shift closer to central Austin.

## 5.6. Policy implications

These behavioral models can be used to forecast the long-term adoption rates of CAV technologies (Bansal and Kockelman, 2015). The forecasted technology adoption rates can help engineers, planners and policymakers modify development projects and processes in commercial and residential areas, along roadways, and across complementary infrastructure. For example, SAV adoption reduces the need for abundant parking, and (private/personal) AV adoption reduces the need for parking in higher-rent locations. More smart vehicles on the roadways enables more dynamic and optimal road pricing policies, as well as better enforcement of speed limits and other desired behaviors. Reliable fleet-mix forecasts can lead to smarter, safer, more connected, and more sustainable ground transportation systems.

Reliable availability of low-cost SAVs (with an option of dynamic ridesharing) may increase the shared vehicle market and reduce private-vehicle ownership. However, such high levels of service can add new demands (and VMT) to the system, resulting in a new for policies that restrain and manage travel (Anderson et al., 2014). Congestion pricing and credit-based congestion pricing, reflecting vehicle size (and, for example, emissions rates) may be needed, using GPS or other technologies, to avoid bottlenecks, excessive delays, added emissions, and other issues associated with different vehicle types. Lower perceived values of travel time may result in far-flung development that places additional loads on our existing roadways, suggesting a new avenue for more proactive land-use transportation planning and policy. This work examined the characteristics of persons and households who are more likely to move away from versus toward the city center; such information can be important in devising long-term land-use balance policies to slow or speed these shifts.

As suggested by this work, individuals anticipate substantial benefits from CAVs, but also perceive hurdles. If potential barriers are not well understood and/or managed thoughtfully, they can slow AV adoption rates to socially sub-optimal

levels. Armed with such information, public agencies can craft specific policies. For example, they may do best to help citizens observe and directly experience CVs, AVs, and CAVs. Such experiences are essential ingredients for widespread and rapid technology diffusion (Rogers, 2010). Anticipating sizable profit implications, many manufacturers and related businesses also have strong interest in creating such opportunities. Key demographic factors and built-environment settings identified here can help businesses and public agencies target groups with lower WTP values, for large-scale, real-world pilots and implementation of successful public-private partnerships.

# 6. Conclusions

Survey results offer many meaningful insights regarding Austinites' perceptions about CAV technology and related aspects. Average WTP for Level 4 AVs (\$7253) is much higher than that of Level 3 AVs (\$3300). More than 80% of respondents are interested in owning Level 4 AVs. For roughly 50% of the population, AV adoption rates appear to depend on adoption rates of friends and neighbors. And more than 80% appear unwilling to pay more for a SAV service than current carsharing and ridesharing companies are charging. More than 75% of respondents indicate interest in adding connectivity to their current vehicles, if the cost is under \$100. Equipment or system failure appears to be the key concern with AV use, while learning how to use the smart vehicle is the least concerning. Respondents believe fewer crashes to be AVs' biggest or most likely benefit, and less congestion to be the least likely benefit. The top two activity picks, while riding in an AV, are looking out the window and talking with friends.

This study also estimated how respondent demographics, built-environment factors, and travel characteristics, impact their opinions about the benefits and concerns for, and adoption of CAVs. For example, regression-model based WTP estimates, SAV adoption rates (under different pricing scenarios), and AV adoption timing collectively suggest that high-income tech-savvy<sup>17</sup> males, living in urban areas and having greater crash experience have more interest in and a higher WTP for these new technologies, with less dependence on friends' adoption rates.<sup>18</sup> Perhaps such individuals are more able to appreciate and evaluate the safety benefits of smart technologies. Surveyed individuals also display a higher inclination to ultimately move closer to central Austin, possibly to enjoy the high-density of low-cost shared fleets (SAVs). In contrast, older licensed drivers expressed less interest in such technologies. They may be concerned about having to learn how to use CAVs and SAVs, and licensed drivers may not be interested in losing the pleasure of driving entirely.

Individuals who drive more were found to be more likely to adopt AVs, with less dependence upon the adoption rates of friends, and willing to spend more to add Level 4 automation and connectivity, but expressed less interest in adding Level 3 automation or using SAVs at a cost of \$3 per mile. This result may be because those who travel longer distances by car can expect to benefit more from safer, more automated, and connected travel with Level 4 technology; and they can perform other activities en route (such as work, reading, and talking with friends). This is not so feasible with Level 3 AVs, because drivers must be ready to take over the job of driving, rather quickly. Consistent with past carsharing studies (e.g., Celsor and Millard-Ball, 2007), respondents who live in more densely populated neighborhoods were more interested in using SAVs under all three pricing scenarios offered here, perhaps due to inconvenient parking facilities and lower vehicle ownership rates in those locations.

Generally, drivers and passengers have different values of travel time, so both are likely to have different WTP to add CAV technologies to their vehicles, among many other differences. The survey did not ask whether each respondent travels mostly as a driver or as a passenger; it did ask whether they have a driving license, and 98% of respondents (all 18 years or older) do. Therefore, it is difficult to know who among these rides mostly as a passenger. Future studies should ask driver-vs.-passenger-type questions to help clarify such distinctions.

We live in a very early stage for public engagement with and understanding of CAVs and SAVs. As communities and individuals learn more about these emerging, vehicle-based technologies, their perceptions and expected or stated behavioral responses are likely to change, in some cases rapidly. More work, similar to that shown here will be very helpful, in all settings. Our society is facing an important and impending transition in transportation. Knowledge of underlying factors across geographies and over time will be important in helping all relevant stakeholders – businesses, regulators, policymakers, and the public at large – coordinate an effective and efficient transformation of our transportation systems.

#### Acknowledgements

The authors thank Amber Chen, Pavle Bujanovic, Jia Lee, and others for helping to develop and distribute the survey. They are grateful to Dr. Varun Rai, Kevin Pappas and Jennifer Hine for editing support, and to several anonymous reviewers for their thoughtful suggestions.

<sup>&</sup>lt;sup>17</sup> A technology-savvy individual is one who has at least one of these attributes: has heard of Google's self-driving car, thinks that ABS is a form of automation, carries smart phone, or is familiar with local carsharing and ridesharing companies.

<sup>&</sup>lt;sup>18</sup> Most of the related covariates are statistically significant and many of these are practically significant in the models for WTP for AVs, adoption rates of SAVs, WTP for CVs, and adoption timing of AVs. Some of them could not achieve threshold |*Z*-value| (1.0) for statistical significance, and therefore, are not included in the tables exhibiting the models' results.
